

# Mini Project 2 - Estimation of obesity levels based on eating habits and physical condition

- This dataset includes data for the estimation of obesity levels in individuals from the countries of **Mexico, Peru and Colombia**, based on their eating habits and physical condition.
- The data contains **17 attributes** and **2111 records**
- The records are labelled with the class variable 'Nobesity' (Obesity Level), that allows classification of the data using the values of **Insufficient Weight, Normal Weight, Overweight Level I, Overweight Level II, Obesity Type I, Obesity Type II and Obesity Type III**.
- 77% of the data was generated synthetically using the Weka tool and the SMOTE filter
- 23% of the data was collected directly from users through a web platform.

# Mini Project 2 - Estimation of obesity levels based on eating habits and physical condition

## **The attributes related with eating habits are:**

- Frequent consumption of high caloric food (FAVC)
- Frequency of consumption of vegetables (FCVC)
- Number of main meals (NCP)
- Consumption of food between meals (CAEC)
- Consumption of water daily (CH20)
- Consumption of alcohol (CALC)

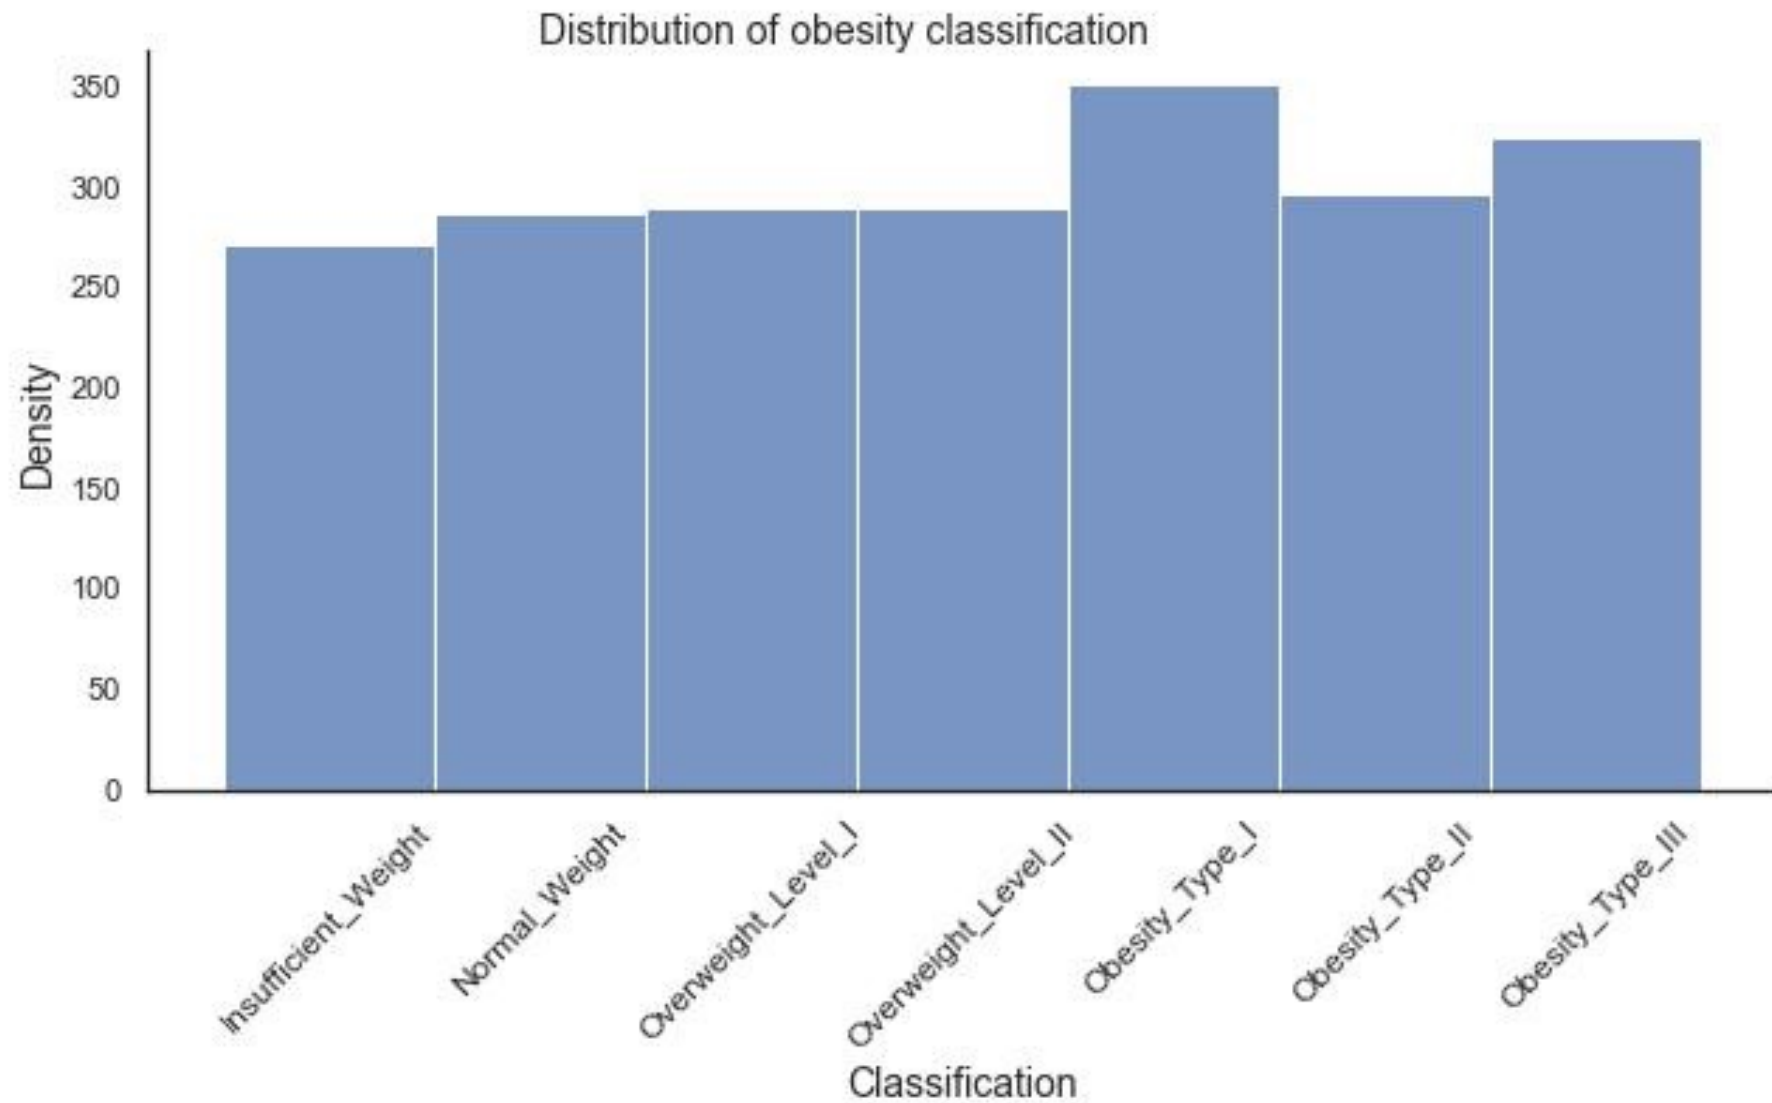

## **Other variables obtained were:**

- Gender
- Age
- Height
- Weight

## **The attributes related with the physical condition are:**

- Calories consumption monitoring (SCC)
- Physical activity frequency (FAF)
- Time using technology devices (TUE)
- Transportation used (MTRANS)

There are seven  
'obesity level'  
classes, with  
roughly equal  
frequencies

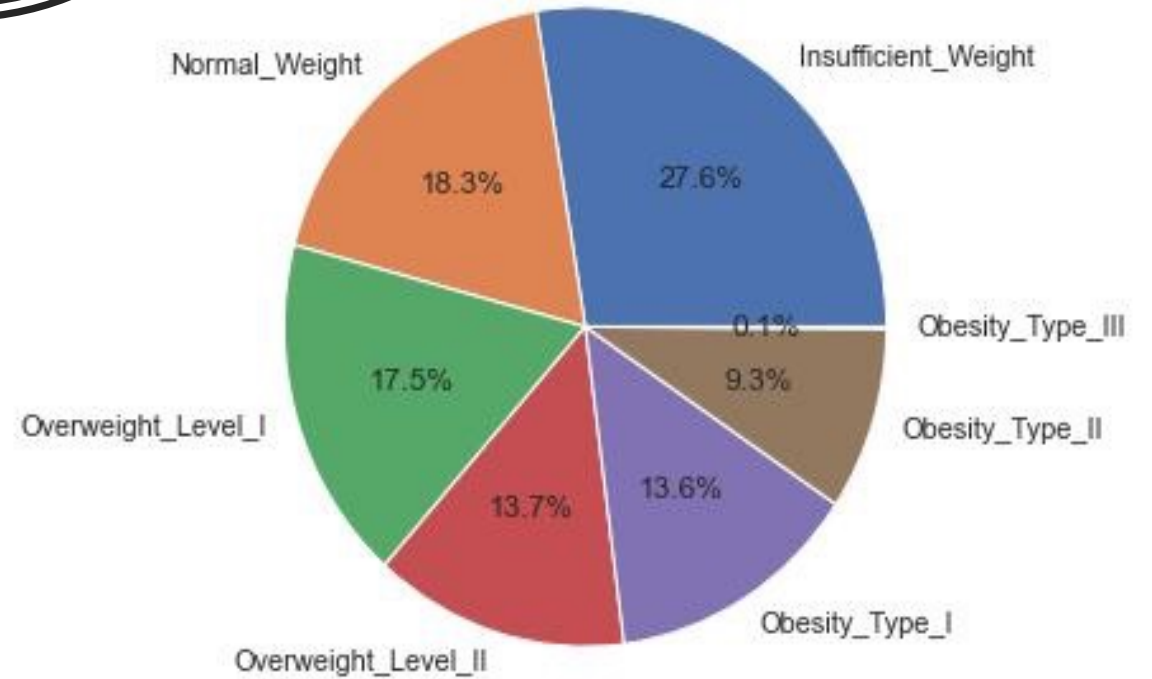

There is no  
difference in  
obesity levels  
between the  
sexes

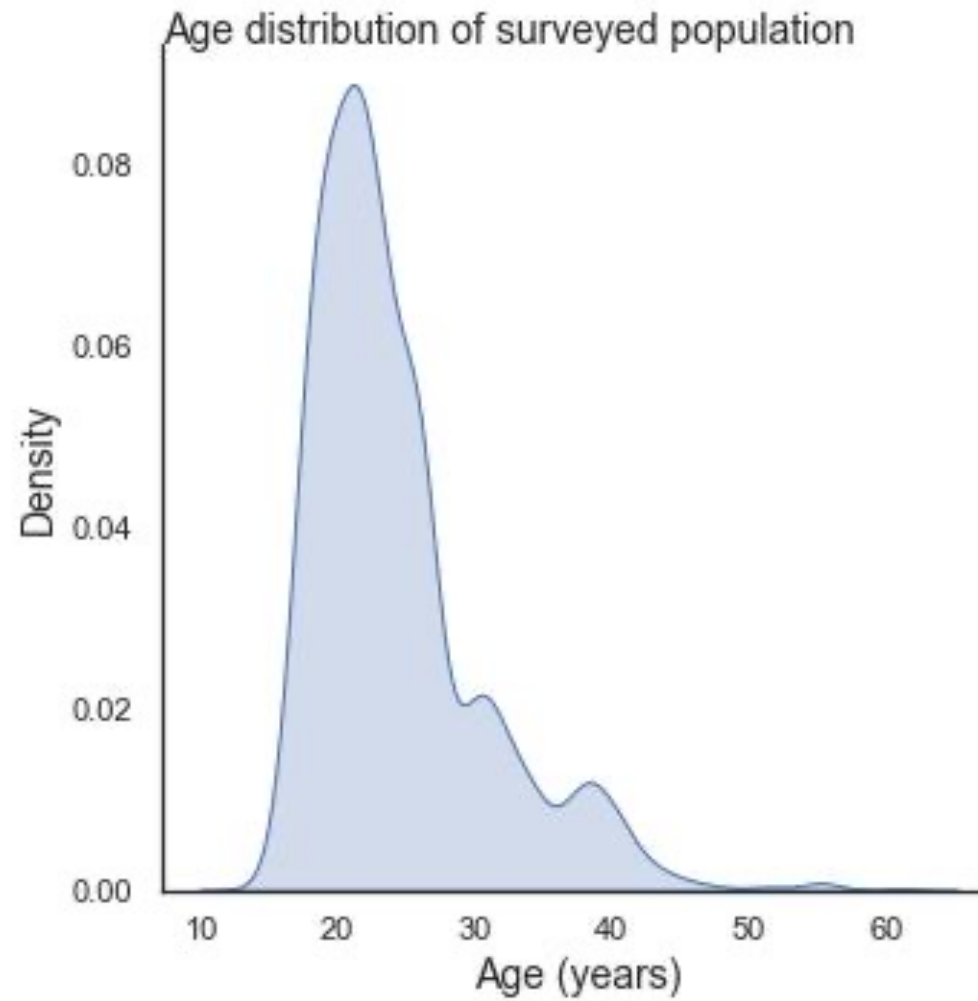

Obesity Classes - Female

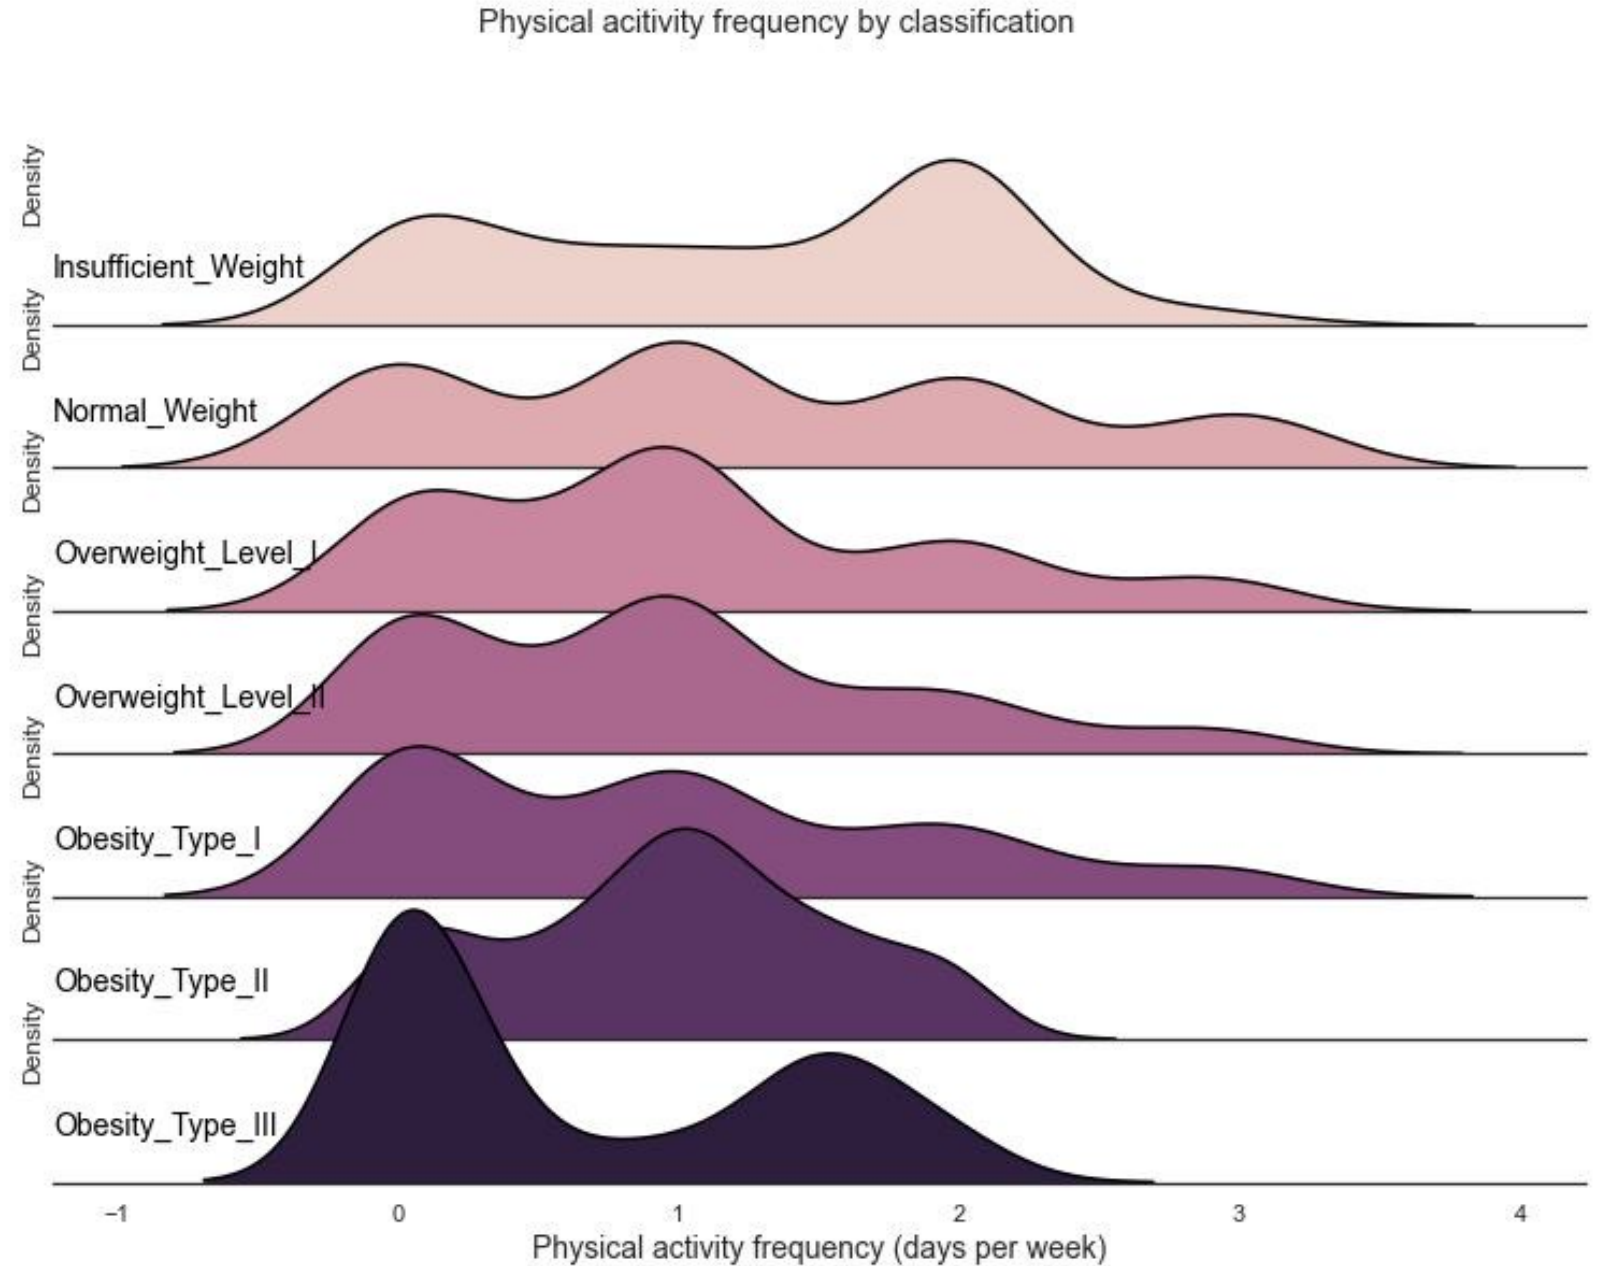

Obesity Classes - Male

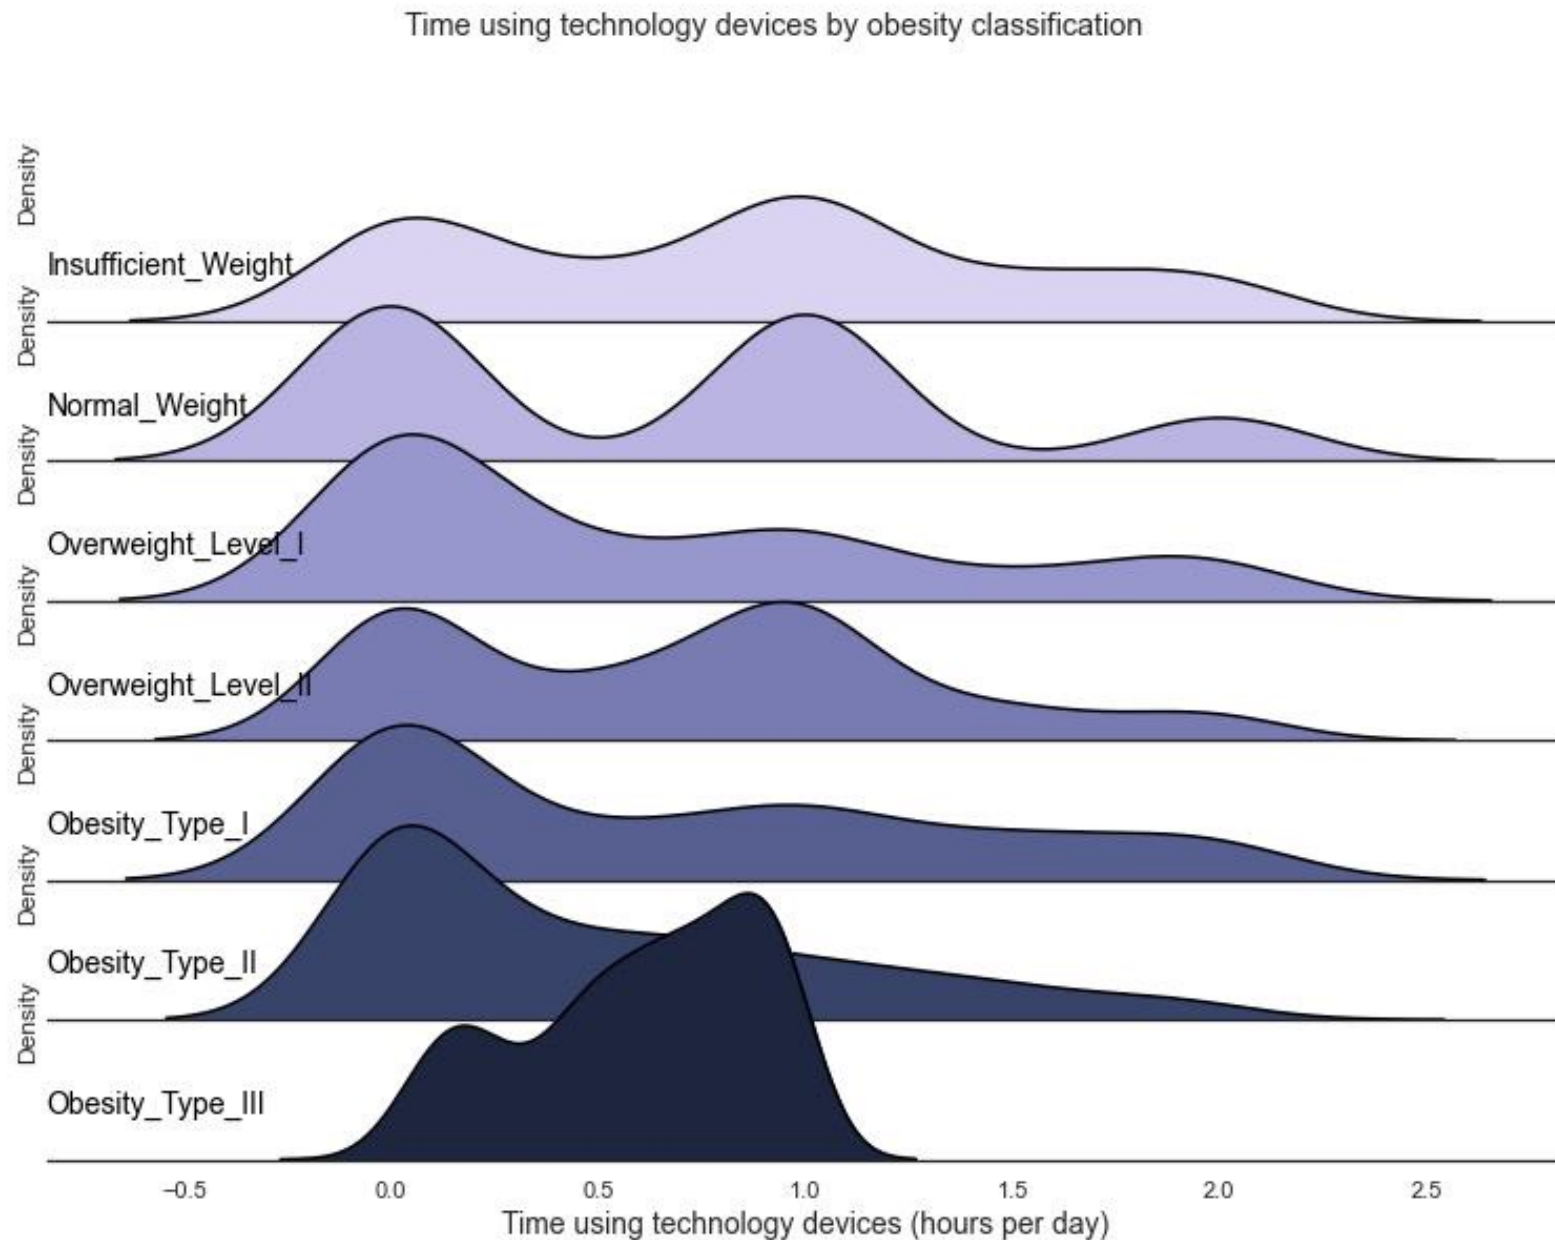

Age distribution  
of the surveyed  
population is  
narrow, with  
most aged 18-30

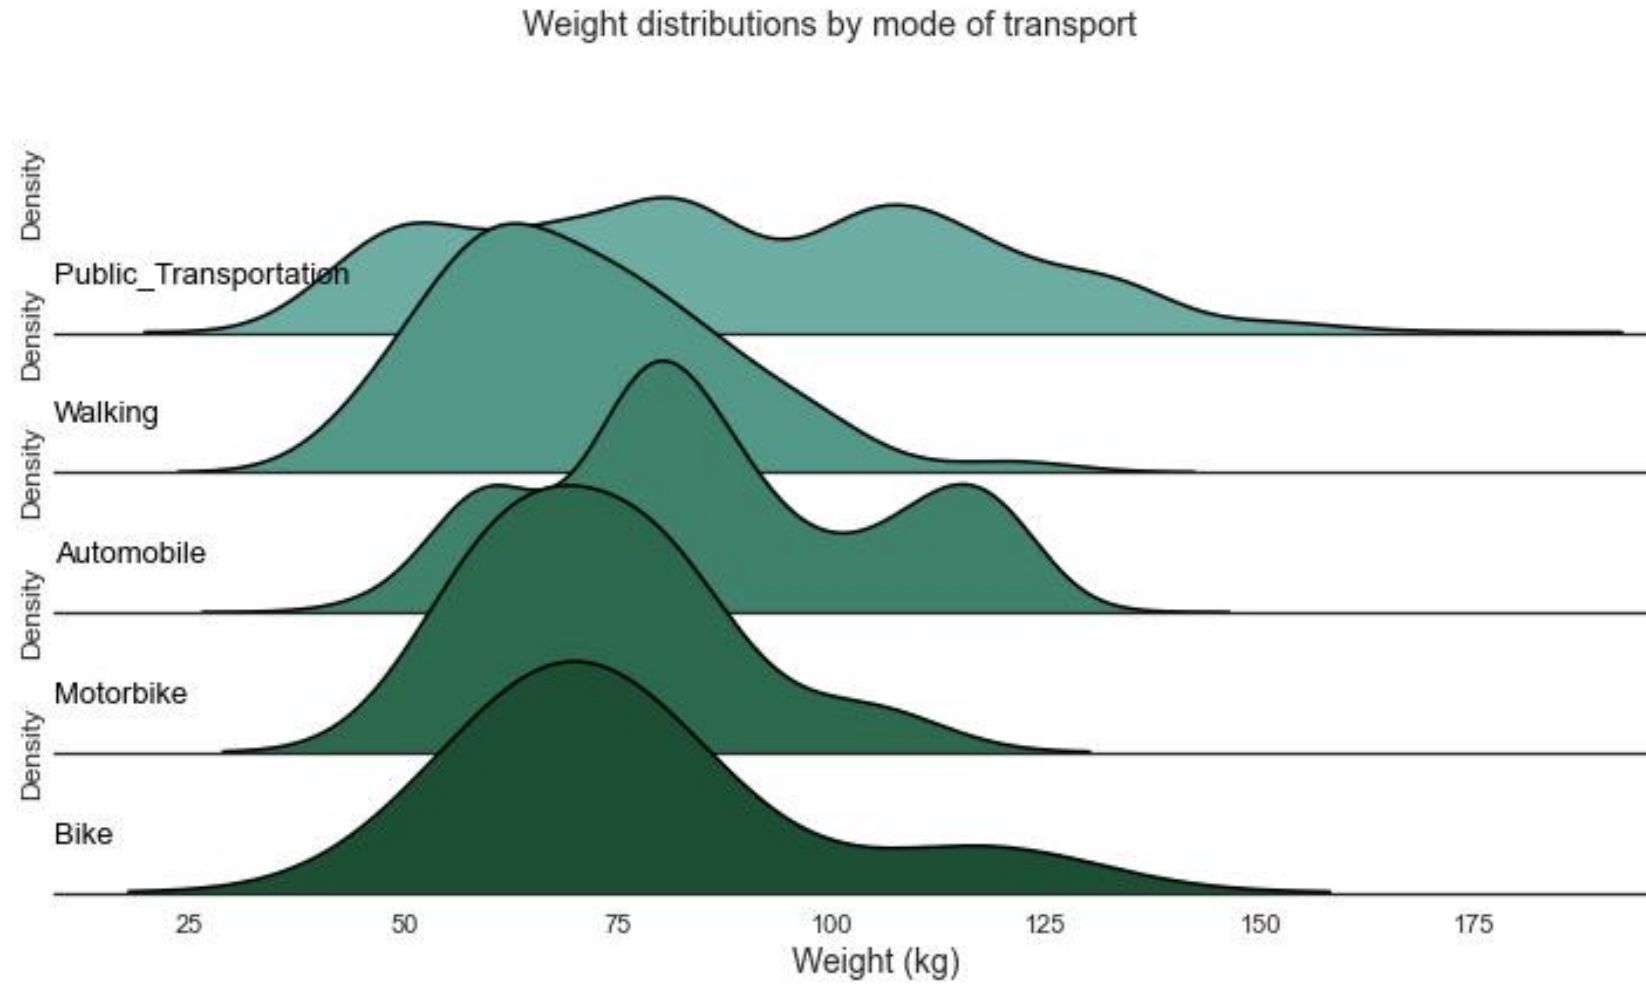

Highest levels of obesity tend to be associated with lower levels of physical activity

But there is no  
obvious  
association  
between level of  
obesity and time  
spent using  
'devices'

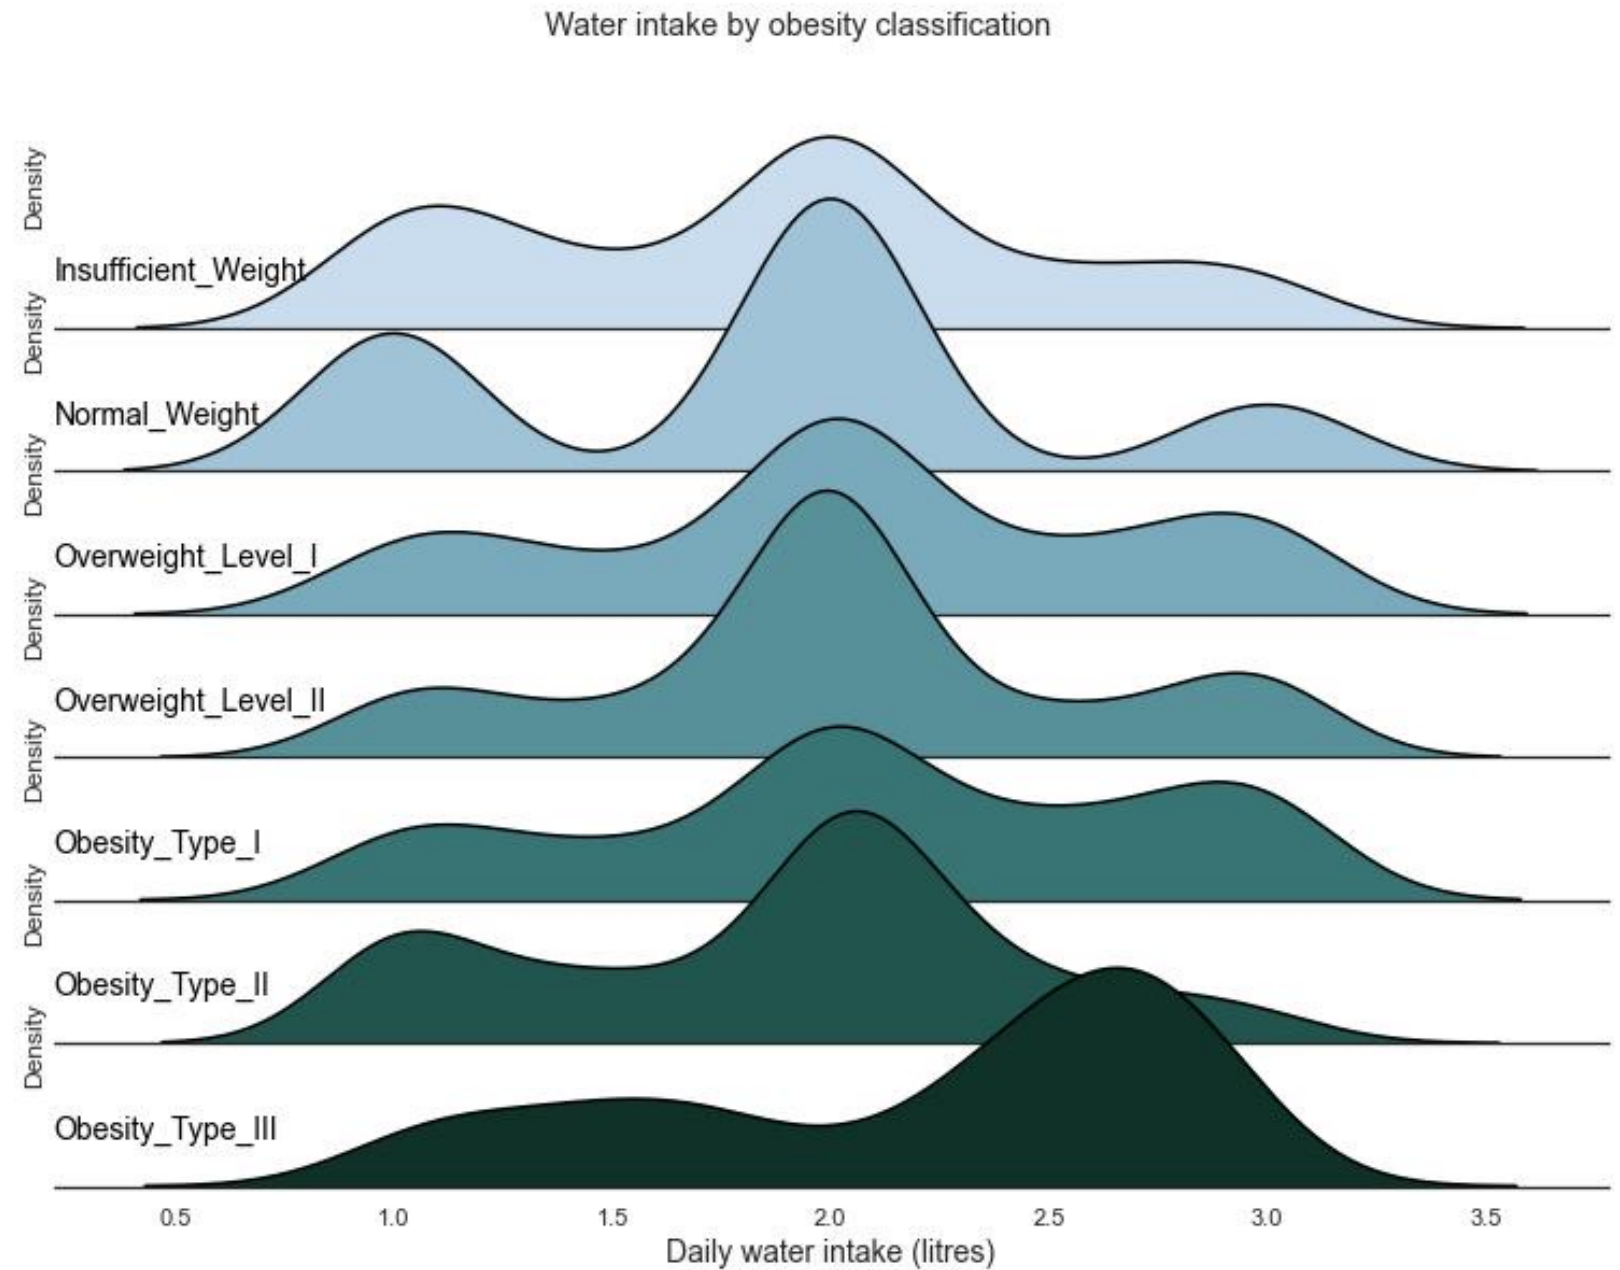

Greater weight tends to be associated with travel by car or public transport, but this is not likely to be a predictive feature

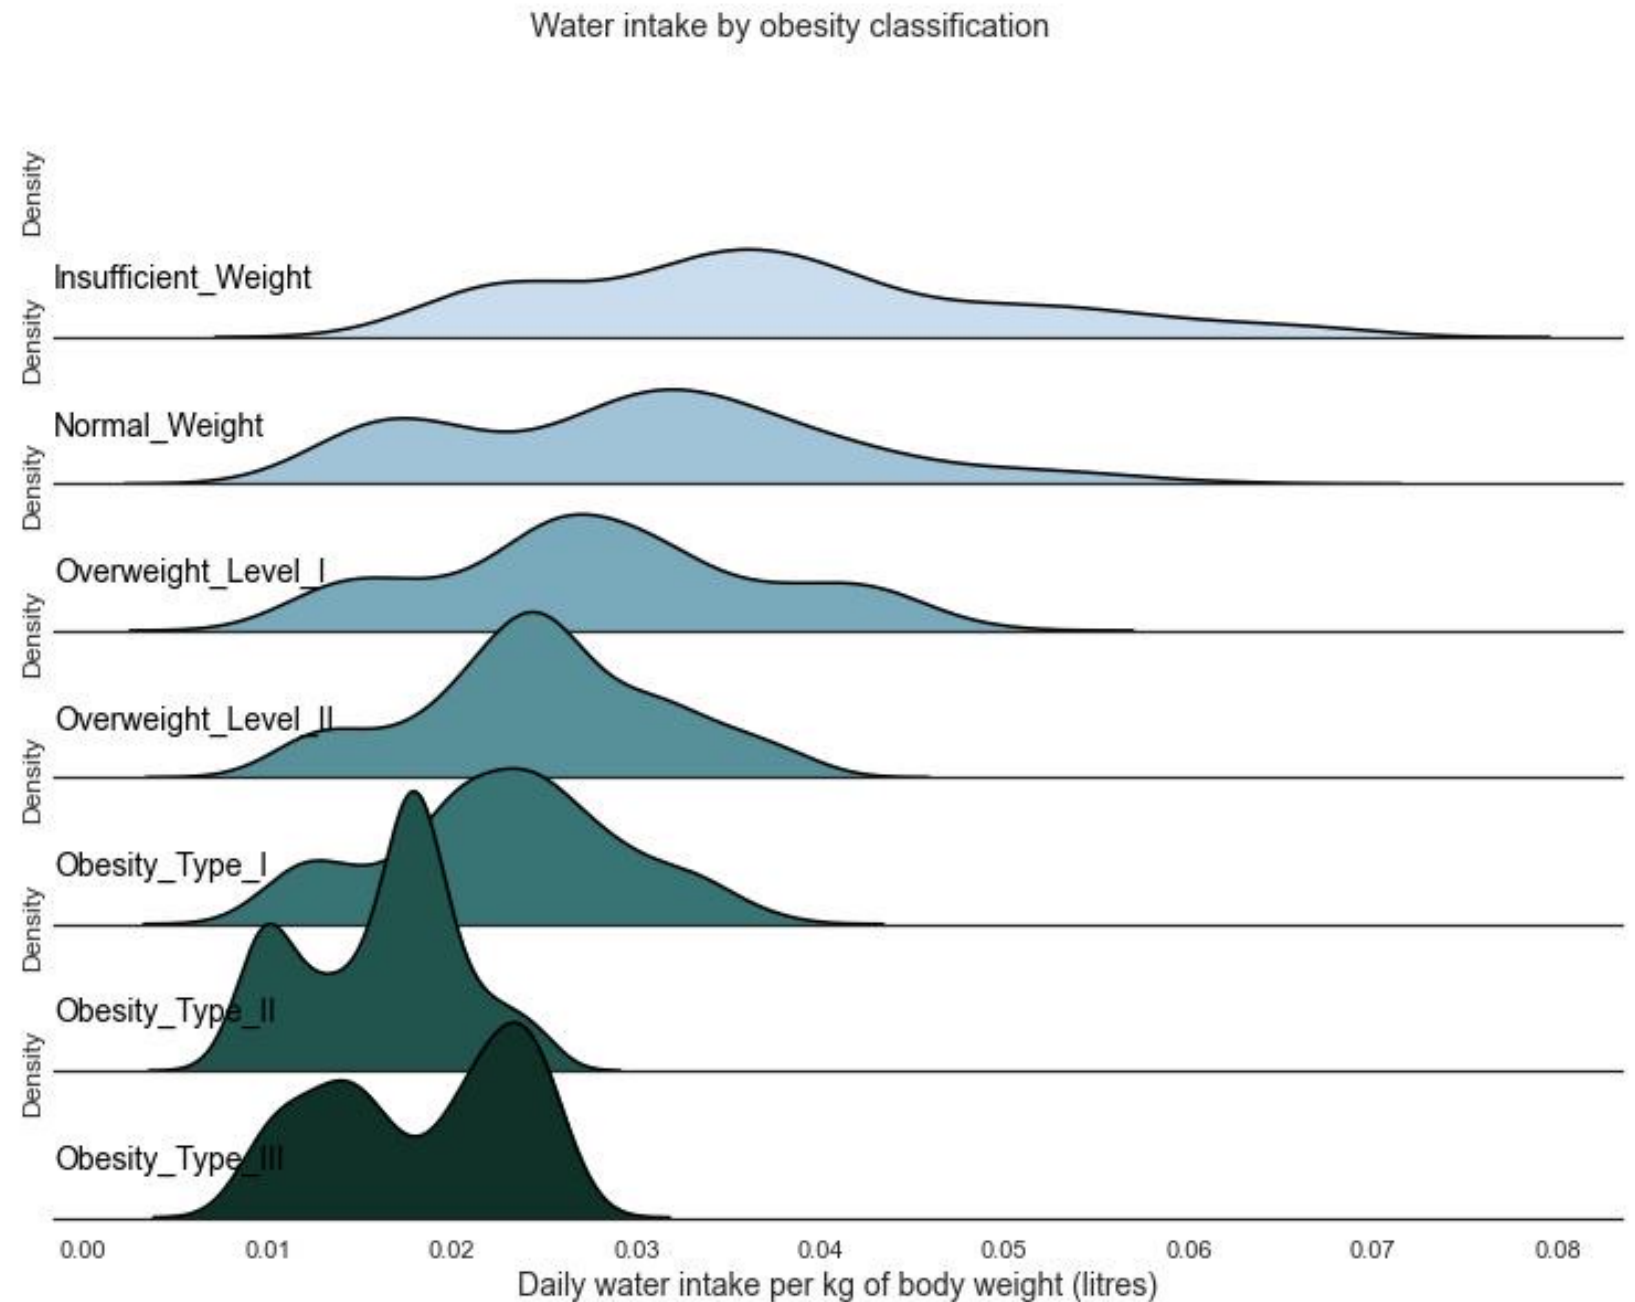

High levels of obesity appeared to be associated with higher daily water intake...

... but this was  
not the case  
when corrected  
for body weight

Feature Creation – 'CH2O\_adj'

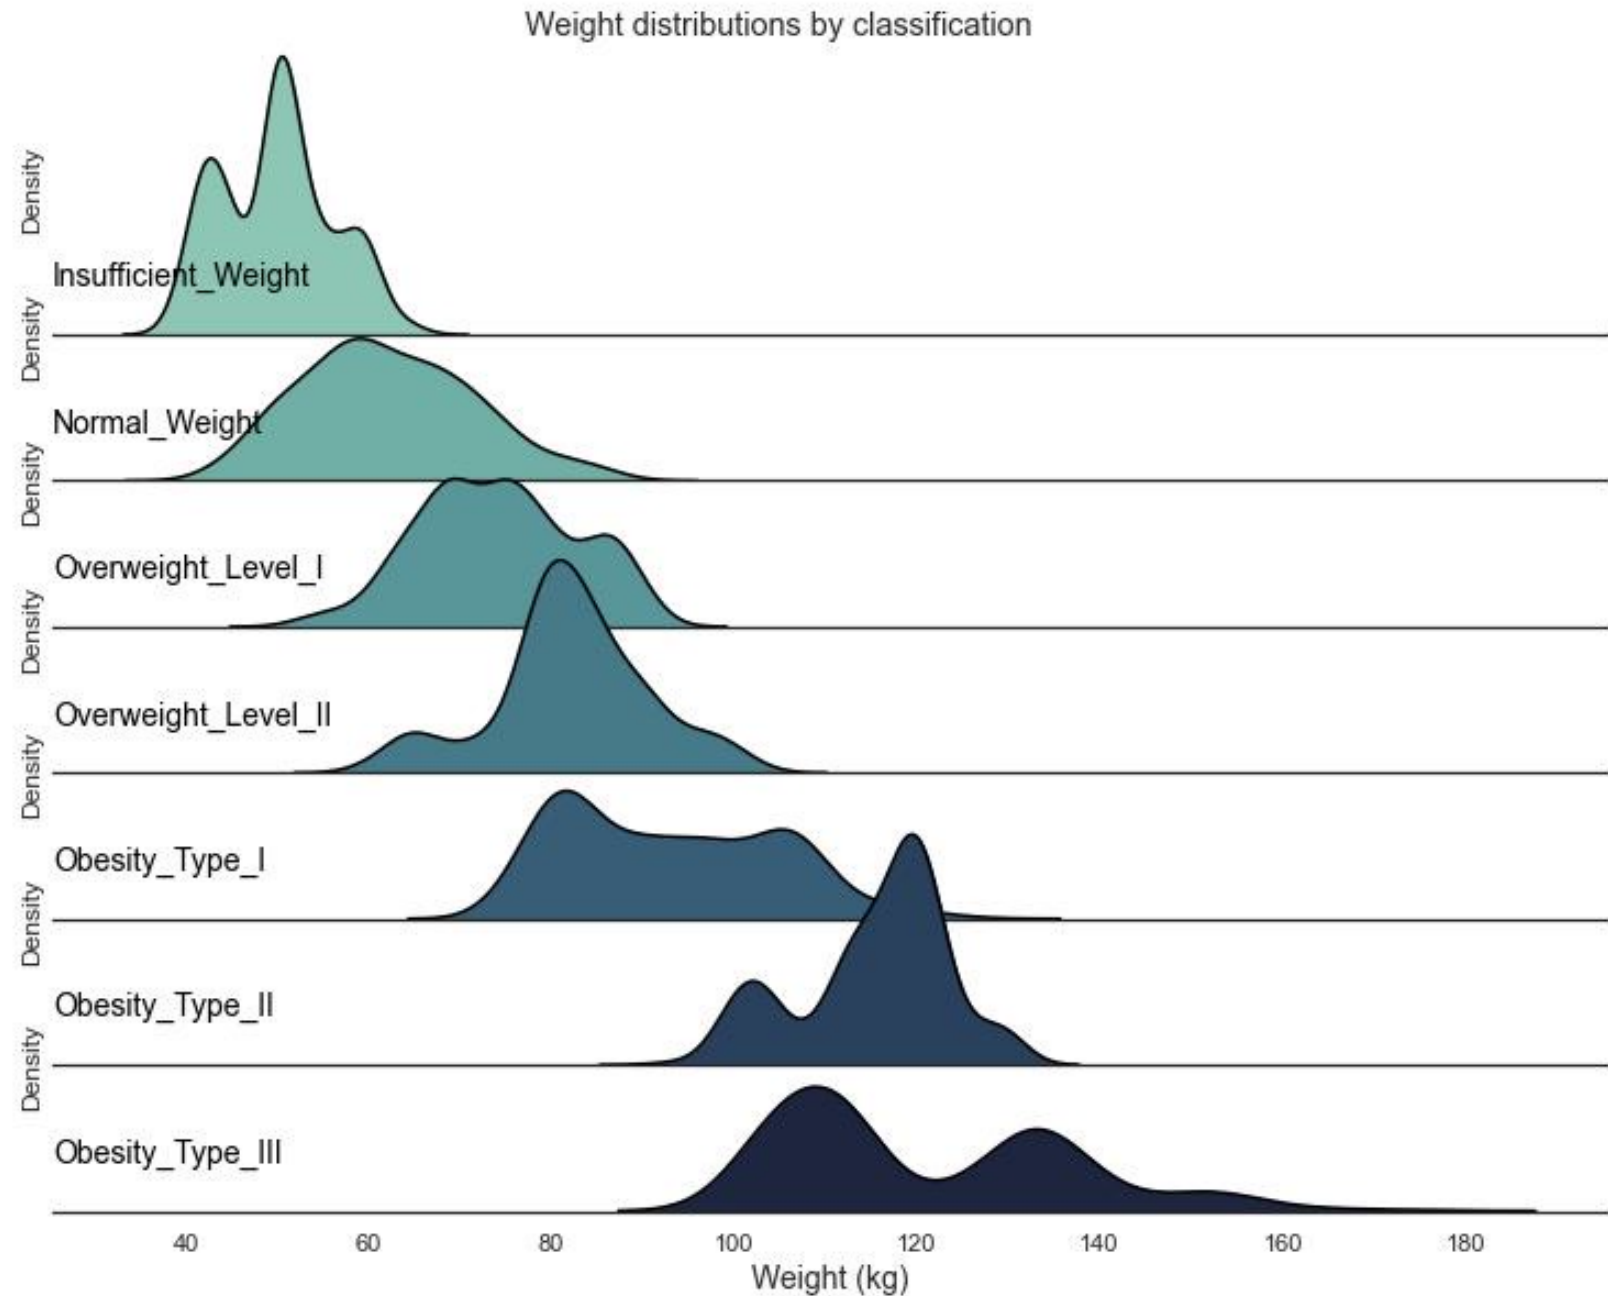

= CH2O (l) / weight (kg)

Mean weight increases with 'body type' classification, but there is significant overlap between the weight distributions for each class

### Feature Creation - BMI

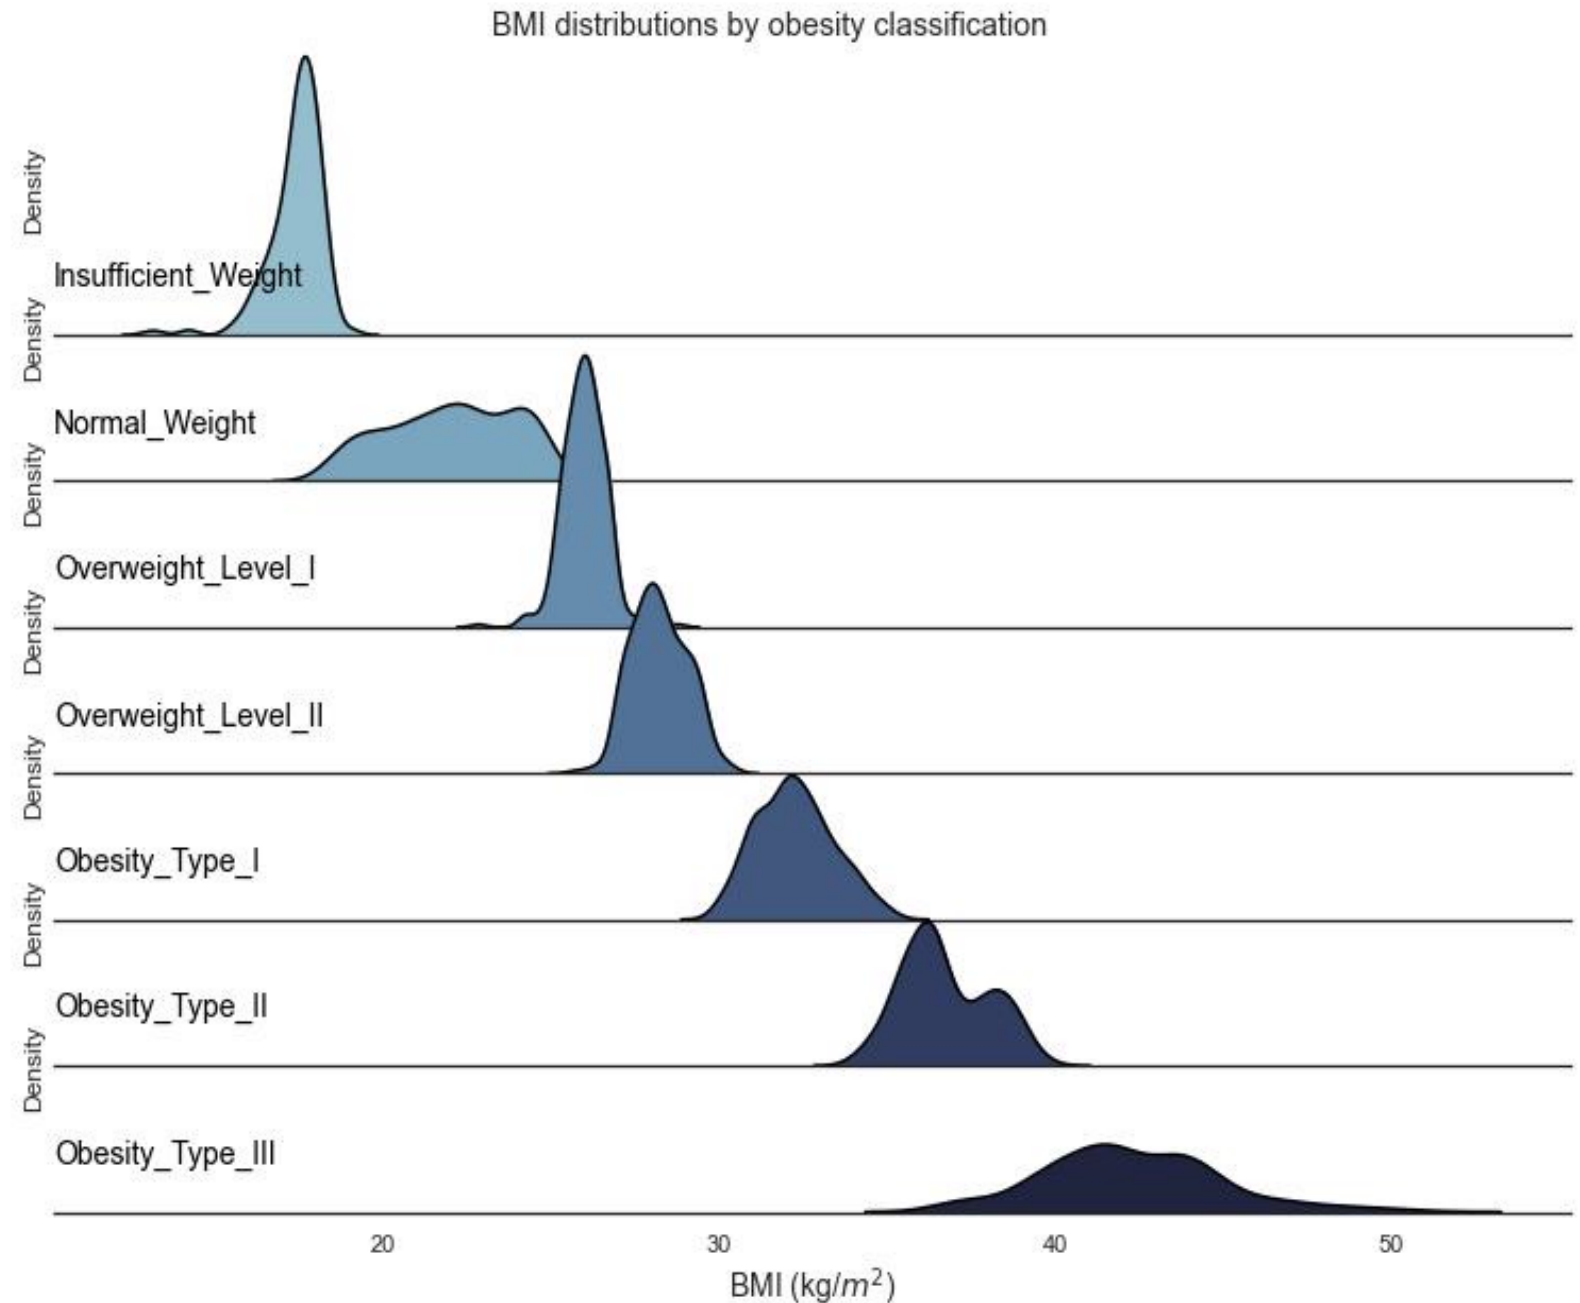

$$\text{BMI} = \text{weight (kg)} / (\text{height (m)})^2$$

BMI increases  
with 'body type'  
classification,  
with much less  
overlap between  
BMI  
distributions for  
each class

### Feature Creation - BMI

$$\text{BMI} = \text{weight (kg)} / (\text{height (m)})^2$$

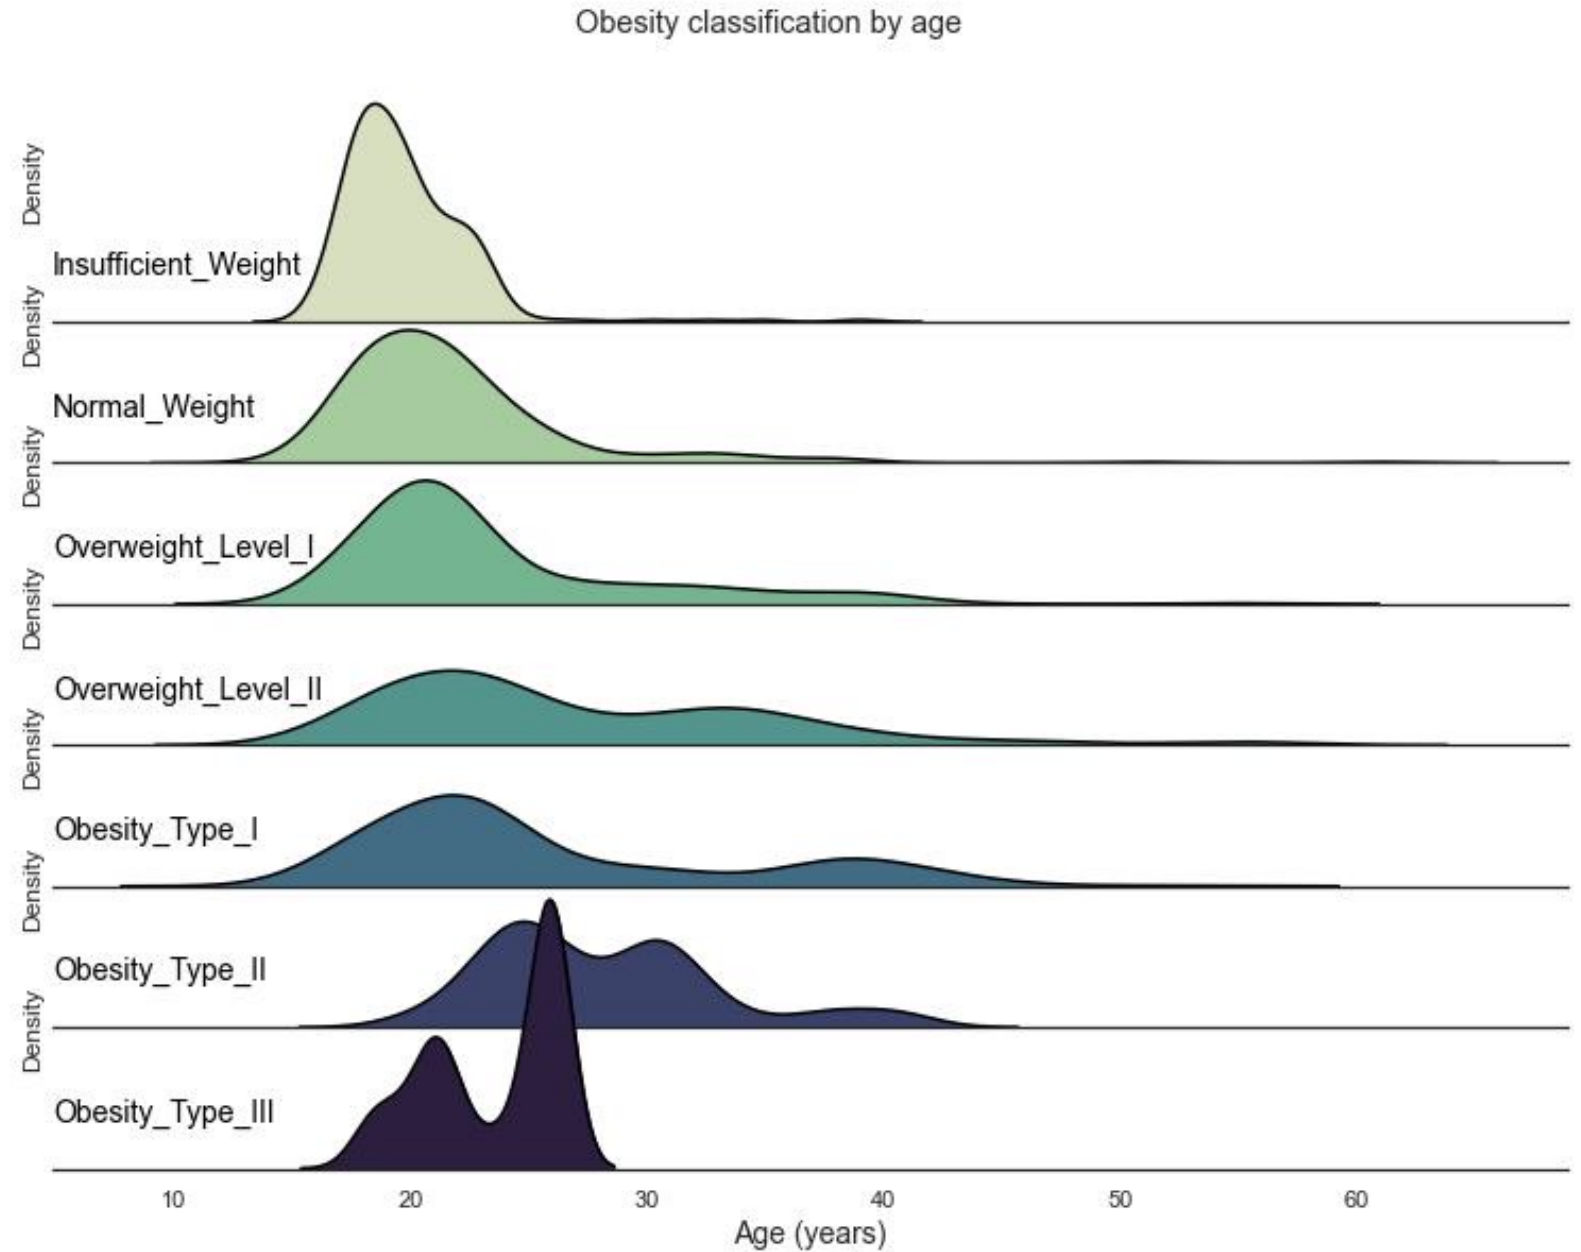

Relationship  
between Weight,  
Height and BMI

Relationship between Weight, Height and BMI

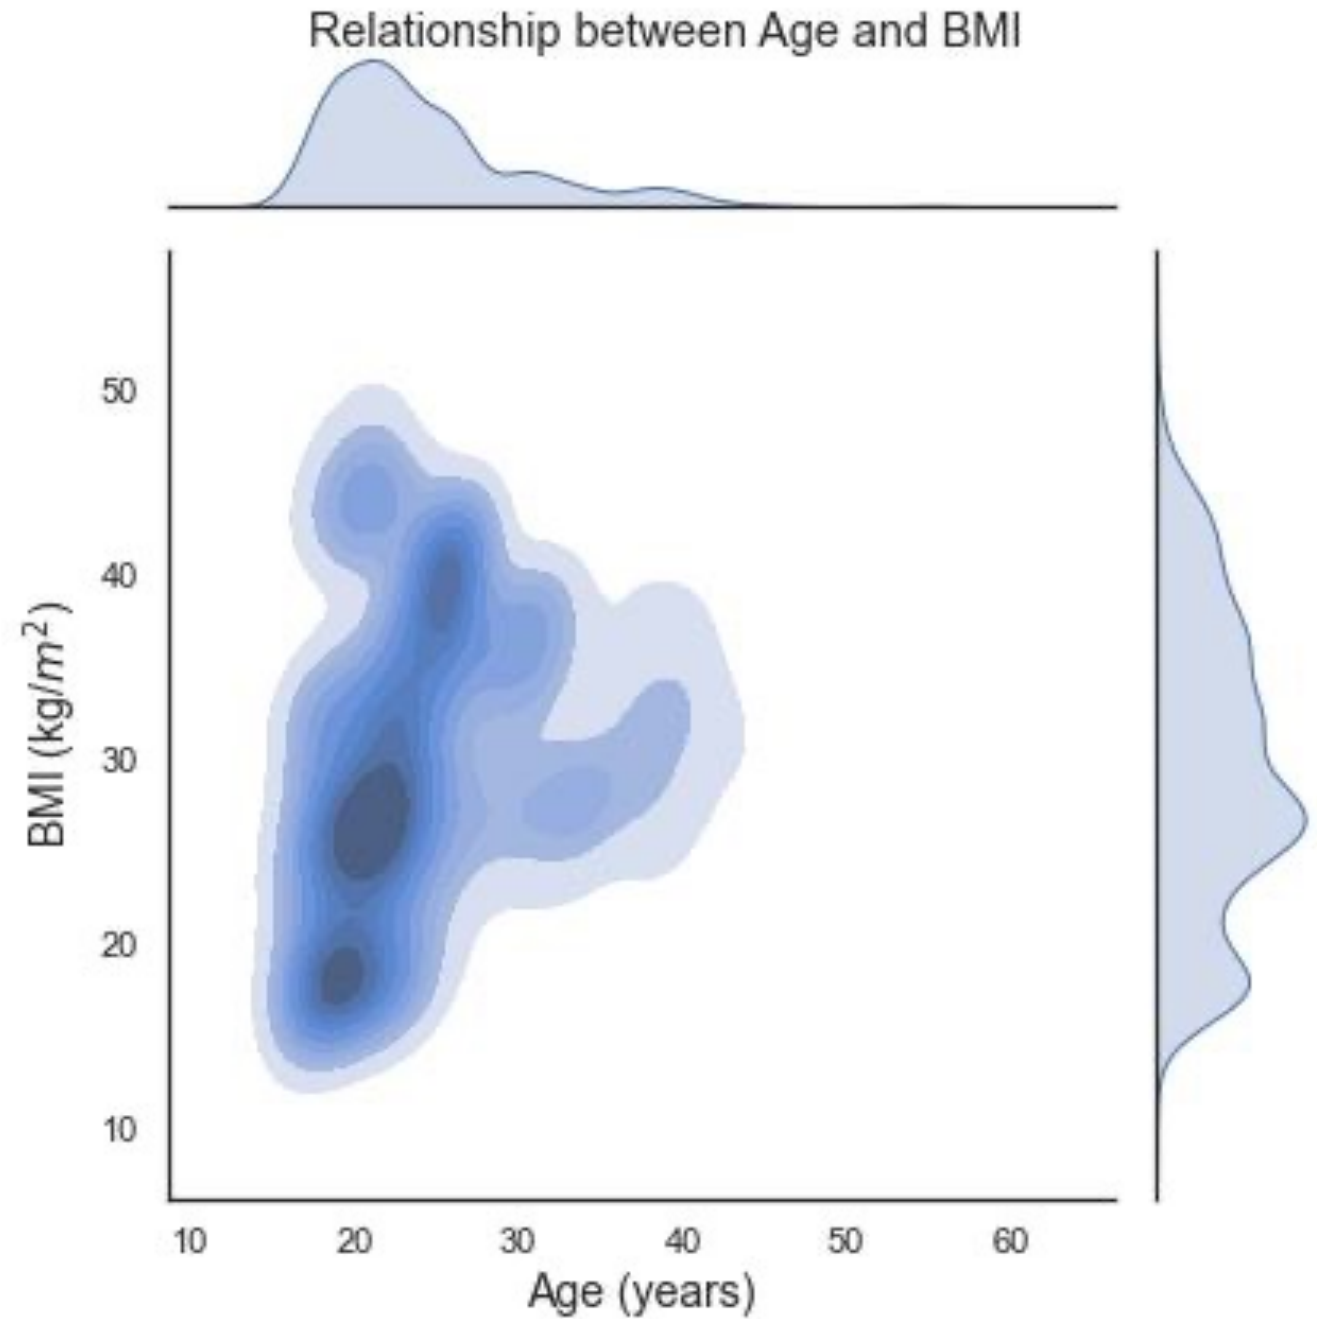

There is a slight  
tendency for  
obesity level to  
increase with  
age...

... and a slight  
tendency for BMI  
to increase with  
age, but with  
such a narrow age  
distribution this is  
not a strong  
correlation

**Business Question 1:**

**Can we predict obesity class based on lifestyle habits and/or physical condition ?**

**Problem type:**

**Classification**

**Models**

Logistic Regression

Support Vector Machine (SVC)

Gaussian Naïve Bayes

**Feature selection**

Best 10 features (by correlation coefficient)

BMI only

All features

**Workflow:**

Categorical data:  
replaced strings  
with binary integers;  
get\_dummies()

Test-Train Split Data  
(20:80)

Standardised  
continuous data  
(StandardScaler())

GridSearchCV() to  
determine optimal  
hyperparameters for  
each model

Pearson correlation coefficient
